1. Introduction

To investigate characteristics of intraseasonal to interannual variations of oceanographic conditions under fast ice in Lützow-Holm Bay, several oceanographic observations and mooring experiments have been carried out since 1998 by the Japanese Antarctic Research Expedition (Aoki and Hashida, 2001). During the 40th Japanese Antarctic Research Expedition (JARE-40) in winter, vertical profiles of temperature, salinity and total inorganic/organic carbon concentrations (TIC/TOC, hereafter) in the water column were occasionally observed at several sites. Chlorophyll *a* biomass in the sea ice was also measured. Continuous records of water temperature, current velocity and direction were obtained with a mooring array, which was composed of temperature recorders, current meters, an automatic water sampler and a time-serial sediment trap.

In this report, we present the vertical profiles of temperature, salinity and TIC/TOC concentrations in water column and chlorophyll *a* biomass in sea ice at several stations in Lützow-Holm Bay, and temporal changes of temperature, as well as current and TIC/TOC concentrations in water at nearly the center of Ongul Strait. We also present information on sea ice conditions.

2. Study area

Sea ice in Lützow-Holm Bay stably covered the sea surface; however, the thickness changed remarkably during JARE-40 over the wintering period. At the beginning of autumn (March) the sea ice thickness in central Ongul Strait was a few ten

centimeters; it grew more than 100 cm during the winter, and then the thickness remained stable until the end of our observations (November). Additional information on the sea ice condition in Lützow-Holm Bay is given by Tsuchiya (2000).

Observations were carried out in Ongul Strait, and at a few stations off Langhovde, Honnør Submarine Valley and Telen Submarine Valley (Fig. 1). Locations of observation stations and observed items are listed in Table 1.

3. Vertical observations and sea ice surveys

Vertical profiles of temperature and salinity were obtained with a CTD-profiler (SBE-19, Seabird Co.). The accuracy given by the manufacturer is 0.01°C in temperature and 0.01 mmho/cm in conductivity. Sensors were calibrated by the manufacturer just before our field use. Correction for the temperature and salinity data using water samples collected from our stations was attempted, however, we could not take reliable samples under severe field conditions. When the water was exposed to the severely cold atmosphere after sampling, the water temperature started to decrease immediately and the water froze even in the water sampler. Therefore, we have listed the raw data obtained in Table 3 and Fig. 2 (see Aoki and Hashida, 2001). Sea ice thickness, snow depth and chlorophyll *a*/phaeo-pigments concentrations in sea ice were also measured and listed in Table 2. For measurement of pigments in the sea ice, an ice core was sampled with an ice auger (inside diameter, *ca.* 7.5 cm) from each observation site. The ice cores were transferred to a laboratory in Syowa Station. Then a whole core from each station was crushed and allowed to melt in several hours in darkness at room temperature (*ca.* 15°C). The melt water from each core was mixed gently, and particles in the melt water (algae) were collected onto a glass fiber filter (GF/F, Whatman Co.). The collected samples were extracted in organic solvent (*N,N*-dimethylformamide, DMF), and chlorophyll *a* and phaeo-pigments were fluorometrically determined (Parsons *et al.*, 1984). Total inorganic/organic carbons (TIC/TOC) were also measured using the water samples collected by vertical sampling with Niskin bottles as shown in Table 4. The Model 1010 TOC Analyzer (OI Analytical Co.) was used for this purpose. TIC and TOC determinations were performed by wet oxidation: TIC was determined by measuring the carbon dioxide released when a sample was acidified by a nondispersive infrared detector (NDIR) that had been calibrated to directly display the mass of carbon dioxide detected. After the sample had been acidified and purged of TIC, sodium persulfate was added and digested the containing TOC into carbon dioxide at 95-100°C. And then the purged carbon

dioxide was detected quantitatively by the NDIR, too. The accuracy given by the manufacturer is <2% of the determined values. Further information about analytical procedure is given elsewhere in the manual supplied by the manufacturer (OI Analytical Co.).

4. Mooring experiment

Mooring experiments were carried out in central Ongul Strait at St. K. The first mooring experiment was started on 14 May and ended on 28 July, and the second experiment was started on 31 August and ended on 26 November 1999. The mooring array design is drawn in Fig. 3. An automatic water sampler (Clean-Water Sampler NWS-11C5, Nichiyu-Giken Co.) with a water temperature recorder (NWT-SN, Nichiyu-Giken Co.) was suspended at depth 10 m and a time-serial sediment trap (SMC-500, Nichiyu-Giken Co.) with a temperature recorder (NWT-SN, Nichiyu-Giken Co.) was installed at 230 m depth. Two Acoustic Doppler Current meters with conductivity, temperature and turbidity sensors (RCM-9, AANDERRA Co.) were fixed at 15 m and 240 m depths. Seasonal temperature data from the two NWT-SN recorders (logged at 10-min interval) are drawn in Fig. 4, and that from the two current meters (logged at 30-min interval) were drawn in Figs. 5 and 6. Figures 5 and 6 describe the seasonal changes of current direction and current speed, respectively. Monthly changes of the direction and speed are also drawn in Fig. 7. Daily averaged temperatures and current velocities from 2 depths are listed in Tables 5 and 6, respectively. An aliquot of water samples obtained from the automatic sampler was used for the determination of TIC/TOC concentrations applying the same determination method as mentioned in the previous section. The results are shown in Table 7 and Fig. 8.

Acknowledgments

Support and cooperation of Drs. S. Ushio, T. Hirawake, T. Odate, K. Watanabe, G. Hashida and S. Aoki (National Institute of Polar Research) in preparing and conducting these observations are deeply appreciated. We also wish to thank Dr. H. Miyaoka, the leader of the wintering party, and all the members of JARE-40 for their help.
