

I. Position of Stations, Surface Elevation and Thickness of the  
Ice Sheet, and Snow Temperature at 10m Depth in the Mizuho Plateau-  
West Enderby Land Area, East Antarctica, 1969-1971

Hiromu SHIMIZU\*, Renji NARUSE\*, Kunio OMOTO\*\*  
and Aiichiro YOSHIMURA\*\*\*

1. Position of Stations

Observers: Kunio Omoto and Aiichiro Yoshimura

Astronomic surveys for determining a geodetic position were conducted at 17 stations on the routes of the inland traverses of JARE 10 and 11, as shown in Table I-1 and Fig. A attached to the end of this volume. For Route S, namely the Syowa-South Pole traverse route, the geodetic positions determined by JARE 9 (Fujiwara *et al.*, 1971), were used as they stood, except at S16, S170 and S240.

Table I-1. Astronomic stations on the traverse routes of JARE 10 and 11 (1969 - 1971).

JARE 9	JARE 10		JARE 11	
S 31	S 170	● B 48	S 16	Y 370
S 70	S 240	C 37	Z 75	Y 475
S 122	A 075	C 80	Mizuho Camp	W 00
S 151	A 001		Y 100	W 55
			Y 200	W 320
4 stations	7 stations		10 stations	
Total	21 stations			

- The position of B48 was surveyed from an astronomic station at a nunatak of Massif D, Yamato Mountains.

\* The Institute of Low Temperature Science, Hokkaido University, Sapporo.

\*\* Department of Geography, Faculty of Science, Tohoku University, Sendai.

\*\*\*Geographical Survey Institute, Ministry of Construction, Azabu Iikura-cho, Minato-ku, Tokyo.

New station S16 was selected by JARE 10 at a position slightly deviated from the position of the old S16 determined previously by JARE 9, and was used as the reference point for the barometric altimetry of the inland traverses of JARE 10 and 11. The position of the new S16 (altitude 553 m) was calculated through a traverse survey from triangulation point No.5 (41.20 m above mean sea level) at East Ongul Island ( $69^{\circ}00'25.1"S$ ,  $39^{\circ}36'50.7"E$ ) by JARE 11.

The geodetic positions of A002 - A164 (S240) were calculated by a triangulation chain from astronomic station A001 ( $71^{\circ}47'28.1"S$ ,  $36^{\circ}12'12.2"E$ ), a south end nunatak of the Yamato Mountains, and those of W01 - W55 through the traverse survey line from astronomic station W00 ( $68^{\circ}36'41.0"S$ ,  $52^{\circ}06'02.0"E$ ), a south peak of the Sandercock Nunataks (see Report VI). The positions of all other stations were interpolated between two neighbouring astronomic stations using navigation records.

Corrections have not been made for disagreements of the values of geodetic positions of stations S16, S170 and S240 surveyed by JARE 10 and 11 with those of their intermediate stations given by JARE 9.

Standard deviations of the geodetic positions of the astronomic stations on the traverse routes were 1.8" in latitude and 25.2" in longitude, by JARE 10's observations; 2.6" in latitude and 11.9" in longitude by JARE 11's observations.

## 2. Surface Elevation

Observers: Kunio Omoto and Hiromu Shimizu

Although there were problems in barometric methods to carry out precise altimetry in a vast field in the presence of the polar cap anticyclone, the surface elevation of the ice sheet was measured by means of barometric altimetry merely because of its simplicity. The single altimeter method was employed throughout the oversnow traverse for altimetry with four barometric altimeters (American Paulin Altimeter MM-1 and/or MT-5).

Readings of elevation differences between two neighboring stations by four altimeters were averaged, and the results were corrected for air temperature. As Route S was travelled 8 times from S16 to S122, and 7 times from S122 to S169 by JARE 10 and 11, all the results of Route S were averaged again. The elevation of the station was calculated by accumulating the elevation differences successively onto the elevation of S16 (553 m). The final results of the surface altimetry along Route S by

JARE 10 and 11 showed a good agreement in a general tendency with those by JARE 9, with a disagreement of 58 m in maximum. From A164 (S240) to A001, and from W00 to W55, the elevation difference between neighboring stations was precisely measured by triangulation and traverse survey, respectively (see Report VI).

Error of closure of an elevation was,

- +21m: at S170 for a circuit track: S170 → S240 → A003 → B48 → S170
- 66m: at S122 for a circuit track: S122 → Mizuho Camp → S169 → S122,
- 8m: at Mizuho Camp for a circuit track: Mizuho Camp → Y200 → W00 → Mizuho Camp,

where the positive sign indicates the final elevation of the junction station appeared higher than the initial elevation. The error of closure was uniformly distributed over the circuit track, except Route A (A164 - A003) and a part of Route W (W00 - W55), where precise measurements were carried out. It is to be noted that A001 and A002 are outside of the circuit track.

### 3. Thickness of the Ice Sheet by Radio Echo Sounding

Observers: Kunio Omoto and Hiromu Shimizu

The thickness of the ice sheet was measured by radio echo sounding along the traverse route of JARE 10 and 11 (Fig. A, Table I-2). The instrument used for the measurement was SPRI (Scott Polar Research Institute) MK II Radio Echo Sounder. Basically, the instrument was a standard radar ranging system with a 35 MHz transmitter and a receiver, equipped with a cathod-ray oscilloscope, Iwasaki's TR Synchroscope SS-3101, for reading echo time. The transmitter produced 500 Watt (peak) pulses with a repetition frequency of 15.625 kHz.

An antenna for transmitting and another for receiving were properly selected by JARE 10 out of a folded-dipole of  $0.7 \lambda$  long, a 4-wire half-wave dipole and 3-element Yagi, depending upon the conditions of the ice sheet. A 3-element Yagi was used by JARE 11 as a common antenna for transmitting and receiving with a TX/RX switch.

An electromagnetic wave velocity of  $171 \text{ m}/\mu\text{s}$  in the ice sheet which was determined by Clough and Bentley (1970) was used to calculate the thickness of the ice sheet from echo time.

#### 4. Snow Temperature at 10 m Depth

Observers: Renji Naruse and Hiromu Shimizu

Snow temperature at 10 m depth was measured to estimate the annual mean air temperature there, with a thermistor-thermometer placed in a hole bored with a SIPRE hand auger, during the oversnow traverses of JARE 10 and 11: JARE 10 made measurements at 7 stations, and JARE 11 at 17 stations. The thermistor-thermometer was calibrated both before and after the traverses with a standard alcoholic thermometer at Syowa Station.

#### 5. Results of the Measurements

Table I-2 gives the geodetic position and elevation of the stations on the oversnow traverse routes of JARE 10 and 11, thickness of the ice sheet and the elevation of the bed rock surface, together with the data of echo time of radio echo sounding, and the snow temperature at 10 m depth.

##### 5.1. Position of stations

Symbols in the table indicate the following:

- : Geodetic positions by astronomic survey by JARE 9.
- : Geodetic positions by astronomic survey by JARE 10 and 11,
- (●) : Geodetic positions of S240 (A164) and A075 calculated by the triangulation chain from A001 were given in Table I-2: These values were in good agreement with those obtained by astronomic surveys at each station.
- ◎ : Geodetic position of B48 was surveyed from an astronomic station at a nunatak, Massif D of the Yamato Mountains.

##### 5.2. Surface elevation

Elevation A: Results by JARE 10 and 11,

Elevation B: Results by JARE 9 for Route S, and those by superposing JARE 10 and 11's data onto JARE 9's for other subdivisional routes.

##### 5.3. Ice thickness and bed rock elevation

The thickness of the ice sheet was calculated by the longest echo

time, if multi-echoes were obtained.

Subtracting the ice thickness from the elevation (A) the elevation of the bed rock surface was calculated where the negative sign indicates that the bed rock surface was below the mean sea level.

#### 5.4. Snow temperature at 10 m depth

- \* : Snow temperature at 5m depth was measured at S160 on November 10, 1969.
- \*\* : Snow temperature at 20m depth was measured at Mizuho Camp on July 22, 1970.
