Energetic electrons precipitated into the atmosphere through pitch angle scattering due to wave-particle interaction cause auroral brightness. Previous studies of pulsating auroral luminosity show a clear correlation with chorus emissions [e.g., *Nishimura et al.*, 2010, *Science*]. However, a detailed correlation study between auroral luminosity, energetic electron precipitation, and chorus emissions has not been performed. In this study, we focus on the process of auroral brightness through wave-particle interaction with ground-based measurements at Syowa Station in Antarctica. We examine characteristics of auroral luminosity by all-sky TV, energetic electron precipitation, and chorus emissions observed at Syowa Station in Antarctica during an auroral event accompanied by pulsating aurora on 17 May 2007. We use the Cosmic Noise Absorption (CNA) data from the imaging riometer which is sensitive to electron precipitation at several tens of keV. An enhancement of distribution of energetic electron precipitation is detected after ~02:53 UT on 17 May 2007. The enhancements of energetic electron precipitation roughly show a correlation with enhancements of chorus emissions and all-sky TV camera. To examine a correlation study focusing on wave-particle interaction, we perform coordinate transform from geographic coordinate to AACGM coordinate. To identify pulsating auroral brightness, we transform auroral images obtained from all-sky TV into auroral movie in AACGM coordinate.

We show characteristics between auroral luminosity, energetic precipitation, and VLF wave activity in AACGM coordinate during the auroral event.
