

## PREFACE

The Japanese Antarctic Research Expedition (JARE) planned a three-year programme of shore-based research, "Marine biological production in the Antarctic coastal ecosystem", between 1982 (JARE-23) and 1984 (JARE-25). This research programme was a part of the international "Biological Investigations of Marine Antarctic Systems and Stocks (BIOMASS)" programme. The JARE-23 was the first year of the three-year programme. The main objective of the JARE-23 was to carry out marine biological investigations as routinely as possible in order to get data of year-round continuity. This volume summarizes the marine biological data obtained in 1982 by the JARE-23. It is requested that due credit be given if data from this volume are quoted, or if information taken herefrom is incorporated in other papers.

## STATION

Five stations were occupied along the transverse line of 69°S latitude on the fast-ice near Syowa Station (69°00'S, 39°35'E). The location of the five stations was chosen according to accessibility and sea depth. Station 1 was located in the narrow and shallow channel of the Kita-no-seto Strait, and Stn 5 was over the deep glacial trough in the Ongul Strait (Fig. 1). In addition, Stn 5' was used for the current meter operation. Data on current measurements are published in JARE Data Reports, No. 102 (Oceanography 5), 1985. In January 1982, the fast-ice surrounding Syowa Station was in good condition for field work and this condition lasted until the end of 1982. Station 4' in Fig. 1 was occupied only one time in January 1983 when the fast-ice around Stn 5 in the Ongul Strait melted heavily and Stn 5 became inaccessible. Stn 4' itself was a thaw-hole.

In January 1983, Stns 1, 2 and 3 were also inaccessible, and thaw-holes near each station were used for observations. Areal photograph in January 1983 is shown in Fig. 2.

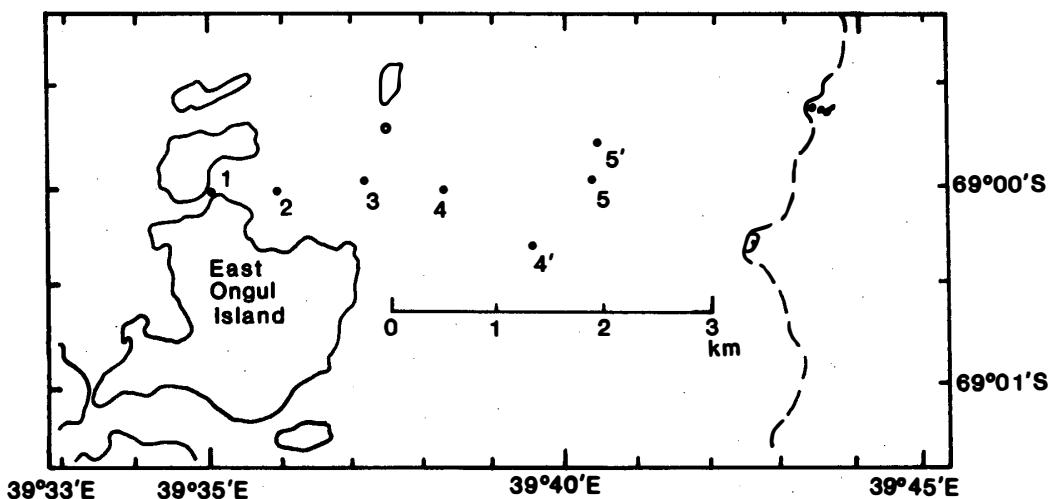

Fig. 1. Locations of oceanographic stations.

Fig. 2. Areal photograph around Stns 1-5 in January 1983.

Thickness of the fast-ice and the sea depth at each station, when stations were occupied, are summarized below.

Station No.	Position	Depth (m)	Thickness of ice(cm)	Date
1	69°00'00"S, 39°35'00"E	10	94	21 Jan. 1982
2	69°00'00"S, 39°36'00"E	25	137	25 Jan. 1982
3	68°59'57"S, 39°37'16"E	50	130	19 Feb. 1982
4	69°00'00"S, 39°38'20"E	160	110	24 Mar. 1982
5	68°59'57"S, 39°40'25"E	675	90	24 Mar. 1982
5'	68°59'46"S, 39°40'42"E	615	80	24 Mar. 1982
4'	69°00'20"S, 39°39'03"E	?	?	13 Jan. 1983

#### FREQUENCY OF OBSERVATION

Water sampling and plankton sampling were done at five stations and we called the combination of these samplings arbitrarily a routine observation. Progress of the routine observation is schematically represented in Fig. 3. Routine observation no. 1 was done at Stns 1 and 2 in late January 1982. A complete set of routine observation at five stations was started in late March and was continued at intervals of 2-3 weeks until December 1982 (routine observation nos 4-19). In January 1983, routine observation nos 20 and 21 were carried out at Stns 1-4 as mentioned before. A total of 21 routine observations was carried out during 13 months between January 1982 and January 1983. In addition, day-night observations were carried out several times as shown in Fig. 3; observation were done two to nine times a day. Periods of current meter operation are also illustrated in Fig. 3. Water and plankton samplings at each station were carried out usually on the same day, except for routine observation nos 4-7.

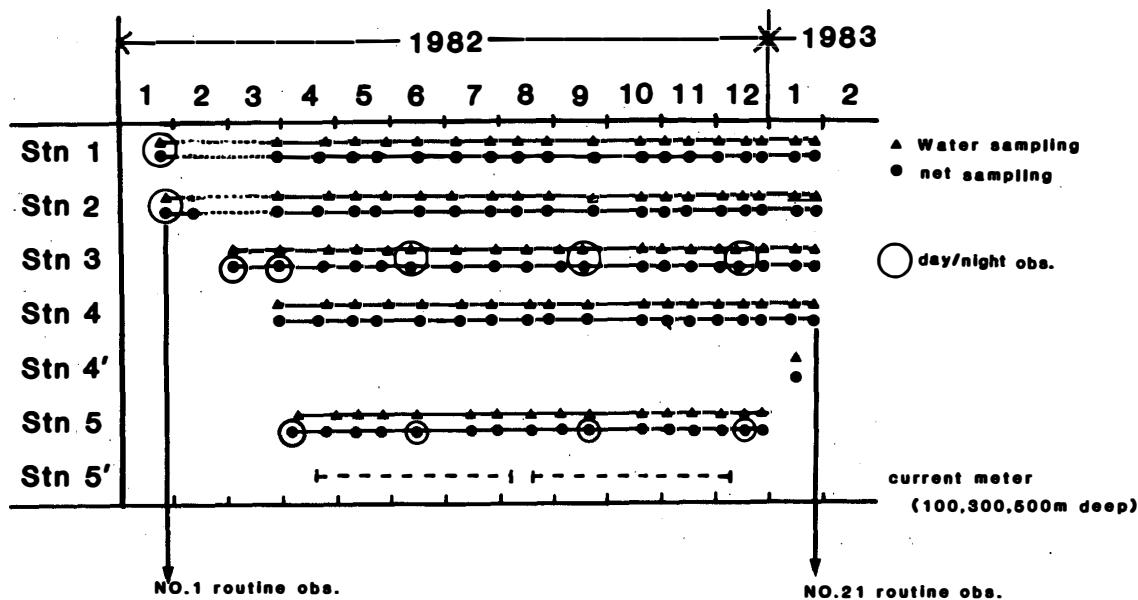

Fig. 3. Progress of routine observation.

Water samplings were made by Nansen and Van Dorn bottles. Methods of water samplings are summarized in Part 1 of this report. Details of plankton samplings with three different methods and their data are summarized in Part 2.

#### OBSERVATION HUT

Samples of water and plankton were processed preliminarily in the observation hut. The hut was mounted on a sledge and was towed to each station by the oversnow vehicle. When the outside temperature was below  $-30^{\circ}\text{C}$ , the room temperature inside the hut was kept at  $+10 - +20^{\circ}\text{C}$  by excess heat from the engine generator (Yammer YSG 3000B). Snapshot of the hut as well as a sledge equipped with an electric winch is shown in Fig. 4.

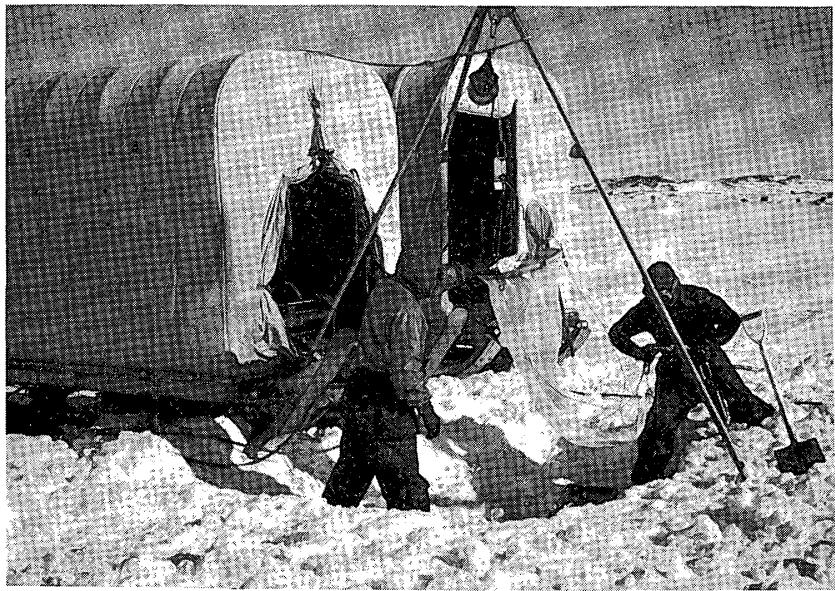

Fig. 4. Snapshot of the observation hut.

#### ACKNOWLEDGMENTS

We express our gratitude to the members of the JARE-23 for their cooperation in field work on the ice. Without their kind support, the large amount of the present data could not be obtained. Routine observation no. 1 at Stns 1 and 2 in January 1982 was carried out in cooperation with Mr. K. Oka and Mr. S. Fuchinoue from Hydrographic Department, Maritime Safety Agency, who measured temperature, salinity, pH and dissolved oxygen. For routine observation nos 20 and 21 in January 1983, we collaborated with the BIOMASS members of the JARE-24 (Dr. E. Takahashi, Dr. H. Satoh, Dr. H. Kanda and Mr. K. Watanabe) who analyzed nutrient samples collected in the routine observation no 21. Our thanks are also due to these persons.

**PART 1. OCEANOGRAPHIC DATA**

## PART 1. OCEANOGRAPHIC DATA

### Method of water sampling

Water samples were collected by two kinds of water bottles, Nansen and Van Dorn bottles. Nansen bottle of 1.3 l capacity was used for oceanographic observation and Van Dorn bottle of 6-l capacity was used for phytoplankton studies. Sampling depths at each station are listed below.

Station No.	Depth (m)
1	0, 2, 4, 6
2	0, 5, 10, 15, 23
3	0, 5, 10, 20, 30, 45
4	0, 10, 25, 50, 75, 100, 150
5	0, 10, 25, 50, 75, 100, 150, 200, 300, 400, 600

To collect water sample from 0 m, the uppermost part of Nansen/Van Dorn bottles was lowered to the level of undersurface of the fast-ice. Depths of subsurface layers were determined in a same manner. Sampling depths and number of sampling depth were changed slightly in December and January when the phytoplankton was abundant. See details in the following tables.

Immediately after the water bottles were retrieved onto the fast-ice, the bottles were brought into the observation hut.

Samples were processed preliminarily inside the hut.

As shown in Fig. 3, the day-night observations were carried out at Stns 1, 2 and 3. Numbers of samplings repeated in one series of routine observation are summarized below.

Station No.	Routine observation No.	Number of sampling
1	1	9
2	1	9
3	8	2
3	13	2
3	18	2

#### Determination of oceanographic parameters

Methods to measure oceanographic parameters including chlorophyll *a* are as follows.

Temperature: A pair of protected reversing thermometers was attached to each Nansen bottle. In addition, when the bottle was lowered below 100 m depth, an unprotected reversing thermometer was attached to check the exact depth of reversal. Both reversing thermometers were read twice to the nearest 0.01°C when the reading of each auxilliary thermometer became stable in the hut. The difference of corrected temperature readings between two protected reversing thermometers was usually within 0.02 °C. When the difference exceeded 0.04 °C or only one reading was employed, temperature data are listed with asterisks in the following tables.

Dissolved oxygen: Water samples from Nansen bottles were drawn into the 300-ml BOD (biological oxygen demand) bottles immediately after the Nansen bottles were brought into the hut. They were the first samples from the Nansen bottles. The BOD bottles were tightly stoppered and brought back to the land laboratory at Syowa Station, where the manganeseous sulphate and alkaline iodide solutions were added to the samples immediately according to a modified Winkler procedure as described by Strickland and Parsons (1968). Dissolved oxygen was analyzed

within several days after sampling. Standard iodate solution (0.01 N KIO<sub>3</sub>) prepared by CSK Standard Service, Sagami Chemical Research Center, Japan, was used for calibrating the thiosulphate solution.

pH: After the oxygen sampling the samples were taken from Nansen bottles by filling a 100-mL wide mouth glass bottle with a tight fitting screw cap. Samples were allowed to room temperature of the laboratory before determination. A Denki Kagaku Keiki Co. Model HG-3 digital pH meter was used for pH determination and was calibrated with standard buffer solutions (Wako Chemicals, Japan).

Salinity: Samples were taken from Nansen bottle by filling a 300-mL amber glass bottle with a rubber stopper. Samples from five stations in the same series of routine observation were kept in the laboratory for several days after sampling. Salinity was determined with an Auto-Lab Model 601-397 MKIII inductive salinometer, and was expressed on a "practical salinity scale" according to the recommendation of the UNESCO/ICES/SCOR/LAPSO Joint Panel on Oceanographic Tables and Standards. The salinometer was calibrated with an international standard sea water. Salinity data with asterisks in the following tables were obtained by correcting the original data, because a possible misreading of the salinometer might have happened.

Nutrient salts: Samples were taken from Nansen bottles by filling a 500-mL narrow mouth polyethylene bottles. Samples were kept frozen in a freezer below -20°C for several days until samplings at five station were completed. After thawing at a laboratory temperature, phosphate-P, nitrate-N and nitrite-N were determined according to the methods described by Strickland and Parsons (1968). The method to measure silicate-Si was

principally based on that of Kato and Kitano (1966), which relies on the direct measurement of the light absorption of the yellow silicomolybdate complex. Standard solutions of blank and required concentrations prepared by CSK Standard Solution Service, Sagami Chemical Research Center, Japan, were used for calibrating the above-mentioned four items. Ammonium-N was analyzed according to Solórzano (1969). Blank and standard solutions for ammonium-N were prepared by the de-ionized water and ammonium chloride ( $\text{NH}_4\text{Cl}$ ). Spectrophotometers of HITACHI model 139 and model 101 were used for measurements of silicate-Si and the other four items, respectively. Silicate data with asterisks from Stns 1 and 2 in the routine observation no. 1 were not comparable to the other data because of the mishandling of the spectrophotometer.

Phytoplankton: Samples were taken from Van Dorn bottles by filling two 1-l wide mouth polyethylene bottles; one bottle for chlorophyll  $\alpha$  determination and another for sample preservation. Standard chlorophyll  $\alpha$  from spinach prepared by Sigma Chemical Co., USA, was determined by two methods of fluorometry (after Saijo and Nishizawa, 1969) and by colorimetry (UNESCO, 1966) using a Shimadzu model RF-510 spectrofluorometer and a HITACHI model 101 spectrophotometer, respectively, in order to obtain values of R and  $f_{ph}$  for the fluorometric determination. Values of R and  $f_{ph}$  were 3.8989 and 0.1038, respectively. An intercalibration of two methods for 50 sets of data obtained in January 1982 revealed a good correlation between two methods as follows:

$$\text{Chl. } \alpha (\mu\text{g/l, fluor.}) = 0.9859 \times \text{Chl. } \alpha (\mu\text{g/l, color.}) - 0.0768$$

$$(N=50, r=0.9910).$$

Between March 1982 and January 1983, one litre of sample water was filtered through a Whatman GF/C glass fiber filter and chlorophyll  $\alpha$  concentration was determined by the fluorometric method only. An aliquot of 100 ml of water was preserved in 2-3 % neutralized formalin solution for the later microscopic examination.

Oceanographic data and chlorophyll  $\alpha$  concentration as well as sample number of preserved samples obtained at Stns 1, 2, 3, 4, 5 and 4' are summarized in Tables 1, 2, 3, 4, 5 and 6, respectively. Oceanographic data from 45 m depth at Stn 3 in the routine observation no. 19 were not comparable to the other data, because the Nansen bottle touched the bottom and the sample water was very turbid.

PART 2. DATA ON PLANKTON SAMPLING

## PART 2. DATA ON PLANKTON SAMPLING

### Methods of plankton samplings

Zooplankton was sampled in three ways: a Norpac standard net (Motoda, 1957) was hauled vertically for collecting mesoplankton, a "NIPR-I" sampler (Fukuchi *et al.*, 1979) was used to take layered samples of mesoplankton and a parasol net was hauled vertically for collecting macroplankton/micronekton. Sampling layers at each station are listed below. Parasol net was used only at Stns 4 and 5. Plankton sampling stations were exactly identical to those of water samplings.

Station No.	Norpac net	"NIPR-I" sampler	Parasol net
1	0-8 m	0, 1, 2, 5, 7 m	-
2	0-25 m	0, 1, 2, 5, 10, 15 m	-
3	0-45 m	0, 1, 2, 5, 10, 25, 39, 45 m	-
4	0-150 m	0, 1, 2, 5, 10, 25, 50, 75, 100, 150 m	0-150 m
5	0-150, 150-300, 300-600 m	0, 1, 2, 5, 10, 25, 50, 75, 100, 150 m	0-660 m

Day-night samplings were also carried out when those of water samplings were done as listed in p. 9. In addition, five times of samplings in routine observation no. 3 at Stn 3 were made.

Immediately after the sampling nets were retrieved onto the fast-ice, they were brought into the observation hut. Net samples were transferred into polyethylene bottles in the hut and they were preserved in about 10 % buffered formalin-sea water when they were brought back to the land laboratory at Syowa Station.

Each sampling method is described in detail as follows.

Norpac net: A Norpac net was a conical net of 45 cm in diameter and 180 cm long. Netting was an NXX 13 of 0.10 mm mesh openings. The net was hauled vertically at five stations from near bottom to the surface at a speed of 0.5-1.0 m/s. Only at Stn 5, divided vertical hauls of 600-300, 300-150 and 150-0 m were carried out. A flow-meter (RGS No. 952) was mounted at the center of the mouth ring of the net to register the volume of water filtered by the net. The flow-meter was calibrated at Stn 4 on 20 October 1982; the flow-meter was attached to the mouth ring of the net from which the net had been removed. The flow-meter was hauled vertically from 150 m depth to the surface at two velocities of 0.5 and 1.0 m/s. Vertical hauls were repeated three times at each velocity and the results are summarized below.

Velocity of haul (m/sec)	Revolution of flow-meter per 0-150 m haul
1.0	1462
1.0	1408
1.0	1451
0.5	1418
0.5	1415
0.5	1418
Average	1428.7

The filtration efficiency ( $F$ ) of the net is expressed as  $F=N/N'$ , where  $N$  is the average number of revolutions per one meter distance with a net and  $N'$  is that of without a net. In the present case,  $N'$  was 9.525 ( $=1428.7/150$  m) as an average of two velocities. Using this value, the filtration efficiency of each net haul was calculated, then the volume of water filtered was

estimated. When the flow-meter was not used at Stns 1 and 2 in the routine observation no. 1, average efficiencies of 97 % and 74 % were applied to net hauls at Stns 1 and 2, respectively. The two values were average efficiencies based on 18 vertical hauls done at two stations in the routine observation nos 4-21. In the case of divided vertical haul at Stn 5, the flow-meter did not work properly at two layers of 600-300 and 300-150 m. An average efficiency of 71 % was calculated from 11 hauls of 150-0 m in the routine observation nos 6-14 and was applied to all hauls at two layers at Stn 5.

Data on the Norpac net hauls at Stns 1, 2, 3, 4, 5 and 4' are listed in Tables 7, 8, 9, 10, 11 and 12 respectively.

"NIPR-I" Sampler: Two types of "NIPR-I" sampler were used to take layered samples between four depths and ten selected depths (see p.59) at Stns 1-5. One type was similar to the prototype as described by Fukuchi et al. (1979) but could be lowered down to 30 m depth. This sampler (mouth diameter, 20 cm; length, 57.5 cm) was operated by a small electric generator such as Honda model E300 (100 V, 300 VA) and was used in the routine observation nos 1, 2 and 19 only. Another type (mouth diameter, 20 cm; length, 80 cm) was a new type modified for operation down to 150 m depth. A submersible electric motor of Hitachi model VCTI-KP (200V, 400W, 3600 rpm) installed in the new sampler was driven by an electric generator of Yammer YSG5EN (5kVA, 4kW). The new sampler was used in the routine observation nos 3-18. In the routine observation nos 20 and 21, no sampling with "NIPR-I" sampler was done.

A conical plankton net of 0.10 mm aperture (NXN 13 netting; diameter, 20 cm; length, 55 cm) was attached to the posterior end

of both samplers. Three minutes of sampling was performed at each depth throughout the routine observations except for the routine observation no. 1 when five minutes sampling was employed.

A flow-meter (General Oceanics model 2030, U.S.A.) with a low-speed propeller (S-2030-R2) was mounted only in the posterior-center of the new sampler to register the volume of water filtered. The volume ( $V$ ) of water filtered by the net could be expressed as  $V=Vst$ , where  $v$  is the water velocity within the sampler,  $s$  is the transverse area of the sampler and  $t$  is the period of sampling. Water velocity ( $v$ ) was calculated from the calibration equation prepared by General Oceanics. When the flow-meter did not work properly, such as freezing or disconnection of propeller, the volume was obtained as an average of the same series of samplings at each station.

Data on the "NIPR-I" sampling at Stns 1, 2, 3, 4 and 5 are listed in Tables 13, 14, 15, 16 and 17, respectively.

Perasol net: Parasol net having a hexagonal mouth was designed for opening-closing operations. Six hinged arms radiating from the center of the mouth could be opened and closed like a parasol. Two different sizes of net were used; a small net with 0.5 m sides, 3.5 m long and mesh sizes of 1.00 and 0.35 mm for the upper and lower parts, respectively, and a large net with 1.0 m sides, 7.0 m long and 2.00 and 1.00 mm mesh sizes. Mouth area of the large and the small nets was 2.598 and 0.650  $m^2$ , respectively. The net was hauled vertically from near bottom to the surface at a speed of 1 m/s only at Stns 4 and 5. The large net was used in the routine observation nos 4 and 5 only.

Data on parasol net hauls at Stns 4 and 5 are listed in Tables 18 and 19, respectively.

Sample processing: Biomass of net sample, such as settling volume and wet weight, was measured for the formalin preserved sample in the land laboratory. Some large animals were removed before biomass measurements. Abbreviations given in the column of "No. of unusual large organisms removed" listed in the following tables are summarized below.

Abb.	Zooplankton	Abb.	Zooplankton
Si.	Siphonophora	Am.	Amphipoda
Me.	Medusae of other Coelenterata	My.	Mysidacea
Ct.	Ctenophora	Eu.	Euphausiacea
Po.	Polychaeta	Pt.	Pteropoda
Ch.	Chaetognatha	Sa.	Salpa
Co.	Copepoda	Fi.	Fish larvae

\* Prototype "NIPR-I" sampler was used.

\*\* Volume was obtained as an average of the same series of sampling.

Table 14. Data on plankton collected by layered sampling with "NIPR-I" type sampler (0.10 mm mesh openings) at Station 2.

\* Prototype "NIPR-I" sampler was used.

\*\* Volume was obtained as an average of the same series of sampling.

Table 15. Data on plankton collected by layered sampling with "NIPR-I" type sampler (0.10 mm mesh openings) at Station 3.

Table 17. Continued.

No. of routine series	Date	Net No.	Sampling time	Sampling depth beneath the ice (m)	Flow-meter reading	Estimated volume of water filtered (m <sup>3</sup> )	Sample No.	Remarks
19	Dec. 27	1	1045-1048	0			2305181	*
		2	1049-1052	1			2305182	*
		3	1053-1056	2			2305183	*
		4	1058-1101	5			2305184	*
		5	1103-1106	10			2305185	*
		6	1108-1111	15			2305186	*
		7	1113-1116	20			2305187	*

\* Prototype "NIPR-I" sampler was used.

\*\* Volume was obtained as an average of the same series of sampling.

Table 18. Data on plankton collected by vertical hauls with PARASOL net at Station 4.

No. of routine series	Date	Time	Length of wire (m)	Angle of wire (°)	Estimated depth of a haul (m)	Settling volume of sample in a haul (mL)	Wet weight in a haul (g)	Sample No.	No. of unusual large organisms removed before settling volume measurement or weighing
