9-10, Kaga 1-chome, Itabashi-ku, Tokyo 173

1. Introduction

The gravity survey in the Mizuho Plateau, East Antarctica has been carried out by the field parties of the Japanese Antarctic Research Expedition (JARE) since 1970 (Yoshida and Yoshimura, 1972; Abe, 1975; Kaminuma and Nagao, 1984). About 500 gravity stations have been established in the area from 1970 to 1981. More than 600 other new gravity stations were established in the Mizuho Plateau by the traverse parties of JARE-23, -24 and -26. The measurements were carried out using the LaCoste-Romberg gravity meters (G-477 and/or G-515). The results of the gravity measurements are described in this report.

2. Measurements

The traverse routes of the three expeditions are shown in Figs. 1-3. The outline of each measurement is given in this

section.

2.1. JARE-23

The details of the measurements are summarized in Table 1. The traverse was conducted in the southern area of the Yamato Mountains at 70-74°S and 35-45°E. The measurements were carried out basically at every 2 km along the route. The reference point of the measurements along this route was No. 214 point of the Yamato Mountain geodetic station on an outcrop set by the Geographical Survey Institute. This gravity point was established by the JARE-22 party in December 1981 (Kaminuma and Nagao, 1984; 982146.443 mgal).

The drift of the gravity meter throughout the measurement period was $0.319 \mu\text{gal}/\text{h}$ and the standard deviation of the solution was $102.07 \mu\text{gal}$.

2.2. JARE-24

Table 2 shows the details of the measurements. The traverse was in the area between the Yamato and Sør Rondane Mountains, through the Belsica Mountains. The gravity stations were established basically at every 2 km along the route. The reference point of the measurements along this route was the Syowa standard gravity station (982525.6 mgal), because no measurements were made on the outcrops in the inland area.

The drift of the gravity meter throughout the measurement period was $4.89 \mu\text{gal}/\text{h}$ and the standard deviation of the solution was $1253.4 \mu\text{gal}$.

2.3. JARE-26

Table 3 shows the details of the measurements. The gravity stations were distributed in the area from 70 to 78°S in latitude and from 30° to 45°E in longitude. For the reference point of the measurements along this route the Syowa gravity standard station was also used. The drift of the gravity meter was $-0.367 \mu\text{gal/h}$ and the standard deviation of the solution was $658.66 \mu\text{gal}$.

3. Determination of Location

The latitude, longitude and elevation of the gravity stations in this report are used the same values as those reported in the JARE Data Reports (Nakawo et al., 1984; Nishio et al., 1986; Fujii et al., 1986; Ageta et al., 1987). The positions of some stations were determined by operating a doppler satellite positioning system (JMR 4A) and the elevation was the height not from the geoid but from the surface of the WGS-72 earth ellipsoid. Navigational data, the azimuth and the distance from one station to the next neighboring station were obtained with a magnetic hand compass and an odometer of a snow vehicle. The longitude and latitude of the non-satellite positioning stations were estimated from the values of both satellite positioning stations and navigational data.

According to the JMR observation at Syowa Station, the elevation of the Tensokuten was determined to be 56.1 m (Shibuya, 1985). The Tensokuten (69°00'S, 39°35'E, 29.18 m, Geographical Survey Institute, 1981) is the first astronomical

control point at Syowa Station. The electric center of the satellite tracking antenna of the JMR observation was installed 46 cm above the Tensokuten. The elevation of the Tensokuten of 56.1 m measured by the JMR was the antenna height from the surface of the WGS-72 ellipsoid. The elevation of the Tensokuten of 29.18 m above mean sea level was the altitude measured by the levelling survey, and seemed to be the altitude from the geoid. This means about 27 m discrepancy between the elevations from the geoid and from the surface of the WGS-72 ellipsoid. This fact suggests that the surface of the WGS-72 ellipsoid is about 27 m above the geoid around Syowa Station. Unfortunately we have no data of the geoid height in the Mizuho Plateau. There are also some difference between the elevation by the JMR observation and the geoid height. If we estimate the difference to be about 27 m in the Mizuho Plateau, this gives about 9 mgal difference of gravity anomalies.

The previous gravity surveys (e.g. Yoshida and Yoshimura, 1972; Abe, 1975; Kaminuma and Nagao, 1984) used conventional altitude, determined by the levelling survey of the inland triangle traverse for calculating the gravity value of elevation correction. Therefore, careful treatment is needed in the data processing using the gravity in this report and the previous reports.

4. Data Reduction

The normal gravity γ was calculated from the following equation of Gravity Formula 1967:

$$\gamma = (A \cdot GE \cdot \cos^2 \phi + B \cdot GP \cdot \sin^2 \phi) / \sqrt{(A^2 \cos^2 \phi + B^2 \sin^2 \phi)}$$

where

A = 6378.14 (km) (equatorial radius of the earth)

B = A (1 - 1/298.257) (polar radius of the earth)

GE = 978031.846 (mgal) (gravity value at the equator)

GP = 983217.728 (mgal) (gravity value at the poles)

ϕ : geographic latitude.

Free-air anomaly Δg_0 and simple Bouguer anomaly $\Delta g_0''$ were calculated by the following equations:

$$\Delta g_0 = g - \gamma + 0.3086 \cdot H + 0.87 - 0.0000965 \cdot H$$

$$\Delta g_0'' = \Delta g_0 - 0.0419 \cdot \rho_1 \cdot (H - IC) - 0.0419 \cdot \rho_2 \cdot IC$$

where g is the gravity value corrected after the instrumental drift and the earth tide at a gravity station in mgal, H the altitude of a gravity station in meters, ρ_1 the density of bedrock (2.67 g/cm^3), IC the thickness of the ice sheet at a gravity station in meters, ρ_2 the density of ice (0.90 g/cm^3). $-0.87 - 0.0000965 \cdot H$ is a term of atmospheric correction. No terrain correction was applied to data reduction. The results are given in Table 4.

The gravity values and elevations along the traverse route of JARE-23 and -24 (SS, YM, RY and KR) are shown in Figs. 4-7. The abscissa are stations and the ordinate are the elevations, and the free-air and Bouguer gravity anomalies.

Free-air and Bouguer anomaly distributions measured by JARE-26 are shown in plain views in Figs. 8 and 9.

5. Accuracy

Usually, before and after the gravity surveys, the gravity measurements were made at the Syowa standard gravity station for the reference. The survey in JARE-23 started with measurement at Syowa Station on 28 August 1982. The second measurement, however, was made at Mizuho Station on 15 September 1982. The third measurement was at the point of YM28 on 12 October 1982. This third measurement was the first one along the traverse route. The survey ended at YM179 on 15 January 1983 and no measurements were made at Syowa Station after the YM179 measurement. The instrumental drift of the survey was estimated from the three different measurements at the YM102 point on 18 October, 17 November and 24 December. The calculated gravity value of Syowa Station by using the No. 214 value to extrapolate the drift ratio was 11.5 mgal larger than the value determined by the IGSN71 measurement.

This large discrepancy suggested that some tears happened during the period between the first and third measurements in the survey. In other words, considering the small drift ratio and the consistent results of the three different measurements at the YM179 point, no tears happened during the period from 18 October 1982 to 24 December, and the accuracy was estimated to be the same order of the standard deviation of the solution. The total accuracy throughout the measurements, therefore, depended on the accuracy of the referenced No. 214 point. The gravity value at No. 214 was measured by JARE-22 in 1981 and the accuracy of the gravity values of the measurements in the

Mizuho Plateau was considered to be 1-2 mgal (Kaminuma and Nagao, 1984). Therefore, the total accuracy of the measurements by JARE-23 was also estimated to be 1-2 mgal.

The survey in JARE-24 started with measurement at Syowa Station on 27 September 1983 and the second measurement was made at the YM102 point on 22 October 1983. The second measurement, about one month after the first one, was actually the first measurement along the route. The last measurement along the route was made at the YM179 point on 31 December 1983. The survey ended with the measurement at Syowa Station on 16 January 1984. The difference of gravity values between two measurements at Syowa Station was 14.42 mgal. Considering the instrumental drift during the traverse survey, this difference was very large. For example, the gravity at the YM102 point measured by JARE-23 was about 3 mgal smaller than that by JARE-24, and the gravity at the YM179 point by JARE-23 was about 0.5 mgal larger than that by JARE-24. The difference may be explained by that the instrumental drift during JARE-24 linearly increased with time. Some tears might have happened in the measurement during the survey. However, we have no way to estimate the place, the time and the value of the tears occurring. Therefore, we have to accept that the 14.42 mgal difference was caused only by the instrumental drift. The accuracy of absolute gravity values in the measurements was estimated to be about 10 mgal.

The measurements at Syowa Station in JARE-26 were made on 17 September 1985 and on 22 January 1986. The difference of

the gravity values between the two measurements was only 0.975 mgal. In this case, we considered that the instrumental drift rate increased negatively at a rate of -0.367 mgal/h during the observation.

In conclusion, the total accuracy of the gravity measurements by JARE-23, -24 and -26 is estimated to be 10 mgal.
