1. Introduction

As part of the Japanese POLEX-South program (1979-1981) conducted by the Japanese Antarctic Research Expedition (JARE), micrometeorological observation on a 30 m tower was done at Mizuho Station. This observation was made in order to investigate the structure of the atmospheric boundary layer and to estimate the heat balance components at the snow surface. The result of the observation made in 1980 by the members of the JARE-21 will be reported in this volume. The preceding data taken in 1979 by the JARE-20 members were already published in JARE Data Reports, No. 62 (Wada et al., 1981). Similar to 1979, along with the micrometeorological observation, radiation observation on the 30 m tower was made and has been published in JARE Data Reports, No. 73 (Ishikawa et al., 1982).

The present report contains the following data of micrometeorological observation:

- (1) Air temperature at 30 m, 16 m, 8 m, 4 m, 2 m, 1 m and 0.5 m levels.
- (2) Snow temperature at 0.1 m, 0.3 m, 0.7 m, 0.9 m, 1.4 m, 3.4 m, 5.4 m and 10.4 m in depth.

- (3) Wind speed at 30 m, 16 m, 8 m, 4 m, 2 m, 1 m and 0.5 m levels.
- (4) Wind direction at 30 m and 2 m levels.
- (5) Thermal flux in snow at 0.2 m, 1.0 m and 1.5 m in depth.
- (6) Dew/frost point temperature at 1.4 m level.

The observers of this program were Tetsuo Ohata, Nobuyoshi Ishikawa and Shun'ichi Kobayashi. Surface meteorological data at Mizuho Station in 1980 were published by Ohata et al. (1981).

2. Instruments and Methods

The diagram of the whole system including the recording system is shown in Fig. 1.

(1) Air temperature

Platinum resistance type thermometers, which were mounted inside a shelter that prevents the direct insolation, were used. It was matched with a Wheatstone Bridge for conversion into voltage value output. Calibration was made by a standard mercury thermometer which had been calibrated by the Japan Meteorological Agency in Tokyo. The values of correction are not shown in this volume.

(2) Snow temperature

A platinum resistance thermometer similar to the ones used for measuring air temperature was installed in a metal pipe and was buried in the snow. It was matched with a Wheatstone Bridge for conversion into voltage value output. The depth of the thermometer changed slightly owing to accumulation and erosion on the snow surface.

(3) Wind speed

Three-cup generator type anemometer was used. At a few times in case of blizzard, hoar frost had developed on the anemometer and the cup stopped rotating. Although the hoar frost was removed whenever this had occurred, there arised a few cases where data were not

obtainable. The relative correction values were obtained for each sensor.

(4) Wind direction

A potential type wind vane was used for this measurement. At a few times, this sensor had troubles similar to the anemometer by hoar frost. The calibration for the wind vane was made by a magnetic compass.

(5) Heat flux in snow

Thermal flux meters manufactured by International Thermal Instrument Co. (USA) were used. The principle of this meter is based upon the measurement of the temperature difference between the upper and bottom surfaces of a thin polyamide-glass plate.

(6) Dew point temperature

This was measured by a mirror-type Hygrometer 660 manufactured by EG&G Co. (USA). This was placed on a pole approximately 100 m from the 30 m tower.

The characteristics of these sensors are shown in Table 1 and a detail report of the sensors can be seen in Mae et al. (1981). There were other elements set on the tower and measured in 1980, but they are omitted in the present volume on account of the inaccuracy in the obtained data.

The height and depth of the sensors from the snow surface were measured several times during the year. These data are shown in Table 2. These measurements were made on the surface near the tower.

3. Data Processing and Evaluation of Data

The recording system was designed and manufactured by Kaijo Denki Co. (Japan). The data were sampled once a minute and the digital records were recorded on a magnetic tape, and simultaneously analog records on a dotting recorder. Most of the data shown

in the present volume are the one hour average value processed from the magnetic tape. The data with asterisk (*) after the LT are the data on the hour read from the record of the dotting recorder. These were adopted when the digital records were not available or when there were too many missing data within the one hour record. The raw data were calibrated with correction values. However, thermometers for snow temperature and heat flux meter were not calibrated in the field.

The micrometeorological data for every hour from January 1 to December 31, 1980 are listed in Table 3. The data are the average value from 01 to 60 minutes of the hour shown under the LT. The data processed from the magnetic tape showed erroneous values in a few cases. These were corrected to accurate values. The data which could not be obtained due to some defaults in the sensors or in the recording systems are shown by 99.9, 88.8 or 0.10E+03 in the table. The records of wind speed and wind direction sometimes showed erroneous values due to development of hoar frost on the sensors. These were left as it is. The periods that can be clearly identified as such periods are the following:

- (1) April 28-29
- (2) May 23-24
- (3) May 28-29
- (4) June 2

There may have been other periods with hoar frost which was not observed.
